and
Dental Health Services
Health Department of WA

AIHW Catalogue No. DEN12

This report is the Western Australian component of the Child Dental Health Survey, a project in which all States and Territories are participating.

The AIHW Dental Statistics and Research Unit (DSRU) is an external unit of the Australian Institute of Health and Welfare, and was established in 1988 at The University of Adelaide. The DSRU was funded to improve the range and quality of dental statistics and research on the dental workforce, dental health status, dental practices and use of dental services.

## THE CHILD DENTAL HEALTH SURVEY - WESTERN AUSTRALIA 1995

## Purpose of this report

Information listed in the tables includes: the age and sex of children in the sample, their deciduous and permanent caries experience, frequency of fissure sealants, children's history of school dental service examinations, and calculus and debris indexes. These data were collected during the 1995 calendar year from WA School Dental Service patients by dental therapists and dentists. A random sampling procedure was used to select one in 13 patients. This was achieved by selecting those children whose birthday was on the 29 th, 30 th or 31 st day of any month. Where children had an unknown date of birth, one in 13 of their records were sampled. Consequently, the data constitute a simple random sample, and no statistical weighting has been applied in their analysis.

The following sections briefly describe each table and provide a simple, summary statement highlighting differences between the 1995 and 1994 data. It is necessary to be cautions in drawing inferences concerning changes between the years. Moreover, no formal hypothesis tests have been undertaken, and descriptions of difference between years are intended as a guide to the reader, rather than an evaluation of trends.

## Table 1: Demographic composition of the sample

The majority of children in the sample ( 77.0 per cent) were aged between 5 and 12 years inclusive, with approximately equivalent numbers in individual ages within this range. However, children aged up to 16 years, or less than 5 years were also represented in substantial numbers. Females and males were represented in similar proportions in all ages.

The distribution of the sample is closely related to the main target groups of children served by the school dental service in WA. The distribution also illustrates that the sample is representative of primary school aged children, rather than all children in the WA.
Moreover, the relatively small numbers of children aged less than five and 17 years or more results in less reliability of computed statistics for those ages, and they have been suppressed where indicated in the following tables. It is also important to note that those children who are outside the main school dental service target groups may differ on key characteristics and are likely to be less representative of their respective age groups in the WA population.

## Changes since 1994

The representation of key age groups in both years are most similar.

Table 3: Deciduous teeth: age-specific caries experience
The mean number of decayed teeth among children aged 5 to 10 years ranges from 0.75 to 0.36 and was lower among older children. There was less variation in mean dmft although the prevalence was slightly higher on average among older children. Mean dmft declined
over the age of 9 , and this must be interpreted in view of the exfoliation of deciduous teeth as children grow older.

The percentage of caries experience due to decay ( $\mathrm{d} / \mathrm{dmft}$ ) shows an age-associated decline, more than halving from 72.2 per cent among 5 year-olds to 25.8 per cent among 10 year-olds. This is the strongest and most consistent age-associated effect for deciduous teeth. By comparison, the percentage of caries-free children ( $\% \mathrm{dmft}=0$ ) shows a more modest reduction from 68.9 per cent among 5 year-olds to 53.5 per cent among 10 year-olds. The percentage of caries free children therefore mirrors the mean dmft prevalence.

## Changes since 1994

Most changes in mean numbers of deciduous teeth with caries experience among 5 to 9 yearolds between 1994 and 1995 were small, and generally do not appear to represent clear trends.

Table 4: Permanent teeth: age-specific caries experience
The mean number of decayed permanent teeth was consistently smaller than the mean number of decayed deciduous teeth, and appeared to increase in children aged 12 years and older. Similarly, the mean DMFT increased quite consistently across age groups. As a consequence, the percentage of DMFT due to decay (D/DMFT) and the percentage caries free ( $\mathrm{DMFT}=0$ ) declined across age groups indicating a lower rate of fillings being placed than the rate of new caries. Age-specific D/DMFT percentages were higher than $\mathrm{d} / \mathrm{dmft}$ percentages in the deciduous dentition below the age of 9 . However this phenomenon is due largely to the very low DMFT values which act as the denominator in D/DMFT and drive the percentage upwards. The mean DMFT score for 12 year old children was 1.04. It is noteworthy that more than 54.8 per cent of children aged 12 or less were caries free.

## Changes since 1994

The average number of decayed teeth appears lower in children aged 13 years and older for 1995 compared to 1994. However, the DMFT for 12 year olds has changed little, being 1.07 in 1994 and 1.04 in 1995. Neither the D/DMFT ratio, or percent with DMFT=0 appear to have varied systematically.

## Table 5: All teeth: age-specific prevalence

Untreated caries in the combined deciduous and permanent dentitions existed for between 23 and 34 per cent of children in the age range 5 to 12 years. The greatest likelihood of untreated decay occurred for 8 year-olds. Based on observations from previous tables, much of this untreated decay can be attributed to the deciduous dentition. Furthermore, it is noteworthy that the most extensive levels of untreated decay ( 4 or more deciduous or permanent teeth) occur in the younger age groups, with approximately 8 per cent of children aged 5 years or less being affected to this extent. This age distribution suggests that the greatest contribution comes from the deciduous dentition.

While more than 95 per cent of children aged 5 to 12 years had no deciduous or permanent teeth missing due to caries, smaller percentages avoid receiving fillings, for which there is an age-associated decline. Similarly, there is a decline in the percentage of children with no caries experience in either deciduous or permanent dentition, from 66.6 per cent at age 5 to 44.8 per cent at age 12. Above the age of 9 , the percentage declines less markedly with age within the range of 41 to 45 per cent. This serves to demonstrate that more than one third of children survive primary school with no experience of dental caries.

## Changes since 1994

The earlier observations of minor changes in deciduous and permanent caries experience carry through to this table which shows insubstantial changes in the percentages of children with $\mathrm{d}+\mathrm{D}=4^{+}$compared with the 1994 data.

Table 6: Fissure sealants: age-specific prevalence
Fissure sealants are moderately prevalent in children aged 8 to 12 years, and at those ages the mean number of fissure sealants exceeds the mean number of decayed teeth, and is close to the mean number of filled teeth. There is evidence of preferential use of fissure sealants among those with caries experience.

## Changes since 1994

The mean number of fissure sealants in 1995 is not consistently different to that observed in 1992 among those aged 5 to 12 years. The percentage of children with fissure sealants is greater among those with caries experience than those without, and the differential between the two groups appears slightly greater across years.

## Table 7: Immediate treatment needs

These data were not collected in WA in 1995.

## Table 8: School Dental Service examinations

This table demonstrates that the great majority (over 90 per cent) of children over the age of 7 years have previously received examinations within the School Dental Service. The figure for 4 year-olds indicates that even among preschool children, a small percentage receives repeated episodes of care from the School Dental Service.

## Changes since 1994

There are negligible differences between 1992 and 1994 in the frequency of first examinations in general, there being a change in the percentage of first examinations for 5 year-old children only.

## Tables 9, 10 and 11

These tables replicate the information from tables 3,4 and 5 respectively for Health Areas within Western Australia. There has been no suppression of estimates with high standard errors, and the reader will need to interpret the data with appropriate care.

Figure 1: Percentage of children with $\mathrm{dmft}=0, \mathrm{DMFT}=0$ and $\mathrm{d}+\mathrm{D}=4+$
This figure presents data contained in tables 3,4 and 5 to summarize the extent of dental health (represented by percentage with no caries experience) and the extent of more extensive untreated decay.

## TABLE 1: DEMOGRAPHIC COMPOSITION OF THE SAMPLE

Data for the Child Dental Health Survey are collected from a stratified random sample of children in all Australian States and Territories. The sampling procedure selects a constant proportion of children for whom date of birth is known by selecting only those children born on particular dates. Within Western Australia, the sampling ratio for children whose date of birth is known is $1: 13$.

State/Territory: Western Australia
Sampling ratio: 1:13
Data for period January-December 1995
Date of report: 25th October 1996

TABLE 2: COUNTRY OF BIRTH (INCLUDING ABORIGINALITY)

These data were not collected in Western Australia during the period January-December 1995.

## TABLE 3: DECIDUOUS TEETH: AGE-SPECIFIC CARIES EXPERIENCE ${ }^{1}$

This table uses State-wide data to describe the dmft index and its components for individual (year of birth) ages. Indices are calculated from data collected over a 12 month period.
Where children received more than one examination during this period, the information derived from examinations other than the first is excluded. Age-specific indices denoted with an asterisk (*) are those in which the relative standard error exceeds 40 per cent, and population estimates of these indices are statistically unreliable.

## TABLE 9: DECIDUOUS TEETH: AGE SPECIFIC CARIES EXPERIENCE

The State-wide data are broken down into regional estimates of the prevalence of the dmf index and its components; a State total is also provided in Table 3. Indexes are calculated from data collected over a 12 month period, and information derived from subsequent examinations of a child in this period is excluded. Age group-specific indexes denoted with an asterisk (*) are those in which the relative standard error exceeds 40 per cent, and population estimates of these indexes are statistically unreliable.

## TABLE 10: PERMANENT TEETH: AGE SPECIFIC CARIES EXPERIENCE

The State-wide data are broken down into regional estimates of the prevalence of the DMF index and its components; a State total is also provided in Table 4. Indexes are calculated from data collected over a 12 month period, and information derived from subsequent examinations of a child in this period is excluded. Age group-specific indexes denoted with an asterisk ( ${ }^{*}$ ) are those in which the relative standard error exceeds 40 per cent, and population estimates of these indexes are statistically unreliable.

State/Territory: Western Australia
Data for period January-December 1995
Date of report: 25th October 1996

[^24]The State-wide data are broken down into regional estimates of the prevalence of the combined components of the dmf and DMF. Indexes are calculated from data collected over a 12 month period, and information derived from subsequent examinations of a child in this period are excluded. Age group-specific indexes denoted with an asterisk (*) are those in which the relative standard error exceeds 40 per cent, and population estimates of these indexes are statistically unreliable.

State/Territory: Western Australia
Sampling ratio: 1:13
Data for period January-December 1995
Date of report: 25th October 1996
